

VerifyHomes App Summary

One-page repo-backed overview generated from Laravel routes, models, migrations, views, and config.

What It Is

VerifyHomes is a Laravel web app for safer landlord-to-tenant rentals, starting with Akure, Ondo State. The repo shows role-based experiences for tenants, landlords, and admin/staff around verified listings and inspection-first rental workflows.

Who It Is For

Primary persona: tenants/renters looking for safer rentals in Akure. Secondary in-repo users: landlords listing properties and admin/staff users handling verification and operations.

What It Does

- Public landing page positions the app around verified listings, inspection first, and safer payments.
- Authentication supports registration, login, password reset, email verification, and profile management.
- Role-based routing gates dedicated dashboards for admin/staff, landlord, tenant, and a generic fallback dashboard.
- Users can carry landlord or tenant profile records linked one-to-one with the main user account.
- Properties store listing details, rent/caution/service charges, room counts, and Akure/Ondo-focused address fields.
- Property records track verification, publication, reviewer, and physical-verification timestamps.
- Property images and property documents support cover images, sorted media, and document review status.

How It Works

- HTTP requests enter Laravel via routes in web.php and auth.php, then flow to Blade views through lightweight controllers.
- EnsureRole middleware plus Spatie permission roles enforce access to admin/staff, landlord, and tenant dashboard areas.
- Eloquent models map user, landlord_profile, tenant_profile, property, property_image, and property_document tables.
- Data persists to the configured database; the default repo config points to SQLite, with MySQL/MariaDB/Postgres/SQL Server options also defined.
- Uploaded file storage is wired for local/private and public disks; S3 config exists, but active cloud usage is Not found in repo.
- Frontend assets are compiled with Vite, Tailwind CSS, and Alpine.js; API endpoints or separate frontend services are Not found in repo.

How To Run

- From the repo root, run composer install and npm install if dependencies are not already present.
- Create .env from .env.example, then run php artisan key:generate.
- Run php artisan migrate --seed to create tables, roles, and the seeded admin account.
- Start local development with composer run dev, then open the app at the APP_URL value.
- Seeded admin login from repo seeder: admin@verifyhomes.test / password123.

Notes

- Role self-selection during registration is Not found in repo.
- Listing submission, search, favorites, and payment-processing implementation are referenced in copy but not present as completed features in this codebase.
